

## Class 3 Lab

### Advanced Database Searching

<http://thegrantlab.org>

Dr. Barry Grant

**Overview:** Searching in databases for homologues of known proteins is a central theme in bioinformatics. The core goals are:

- High **sensitivity** - that is, detecting even very distant relationships, and
- High **selectivity** - namely, minimizing the number of reported 'hits' that are not true homologues.

All database search methods involve a trade-off between *sensitivity*, *selectivity* and *performance*. Important questions to ask include does the method find all or most of the examples that are actually present, or does it miss a large fraction? Conversely, how many of the 'hits' that it reports are incorrect? Finally does the approach scale to the tractable analysis of large datasets?

In this hands-on session we will explore the detection limits of conventional BLAST and introduce more sensitive (but often more time consuming) approaches including **Profiles**, **PSI-BLAST** and **Hidden Markov Models** (HMMs).

### Section 1: The limits of using BLAST for remote homologue detection

Let's return to the HBB protein that we explored in a previous class and see if we can find distantly related myoglobin and neuroglobin using this as a BLAST query.

```
>gi|4504349|ref|NP_000509.1| hemoglobin subunit beta [Homo sapiens]
MVHLTPEEKSAVTALWGKVNVDEVGGEALGRLLVVYPWTQRFFESFGDLSTPDAVMGNPKVKAHGKKVLG
AFSDGLAHLNLTGKTFATLSSELHCDKLHVDPENFRLLGNVLVCVLAHHFGKEFTPPVQAAAYQKVAVGVA
ALAHKYH
```

After selecting **blastp** and entering the sequence, be sure to change the search database to "**refseq-protein**" and restrict our search organism to only **humans** (taxid: 9605). This will help focus our results to highlight distant homologs in humans.

**Q1.** What homologs did you find with this simple blastp search? Note their *percent identities*, *coverage* and *E-values*.

hemoglobin subunit epsilon [Homo sapiens]:  
% identities: 75.51% ; coverage: 100% ;  
e-values: 2e-82

Now we could try changing the **Algorithm parameters** on the submission page to increase the number of hits reported. To do this you can click on the **Edit and Resubmit** link at the top left of your results page.

**Q2.** Try increasing the **Expect threshold** for your blasts search. What new hits were reported? What about their alignment statistics? Do you trust these matches?

Many useful ‘rules of thumb’ are expressed in terms of percent identity. If two proteins have more than 45% identical residues in their optimal alignment they typically have very similar structures and are likely to have a similar function. If two proteins have more than 25% identical residues (but less than 45% identity), they are likely to have a similar general folding pattern. Note that we will expand on the basis of this important *sequence > structure > function* relationship in a subsequent class unit.

Observations of a lower degree of sequence similarity cannot however rule out homology. Our very own Russ Doolittle ( <http://biology.ucsd.edu/research/faculty/rdoolittle> ) defined the region between 18-25% sequence identity as the “**twilight zone**” in which the suggestion of homology is tantalizing but dangerous. Below the twilight zone is a region where pairwise sequence alignments tell us very little - sometimes called the “midnight zone”.

## **Section 2: Using PSI-BLAST**

Although the twilight zone is a treacherous region, we are not entirely helpless. In deciding whether there is a genuine relationship, the ‘*texture*’ of the alignment is important - essentially are the similar amino-acids isolated and scattered throughout the sequences, or are there characteristic ‘icebergs’ - local regions of high similarity seen in many distant sequences that may correspond to a shared active site or other functional motif?

Lets return to your previous BLAST submission page with the HBB example from before. This time select the **PSI-BLAST** algorithm from the ‘Program Selection’ options section (see image below). Other settings should be as before (remember to reset your Expect threshold to default if you changed this previously) and use **refseq\_protein** and search only in humans again.

**Q3.** The first iteration should be similar to your previous blastp search. Did you find any new potential homologs that you did not see previously?

Yes. The new potential homologs include cytoglobin [Homo sapiens], cytoglobin isoform X1 [Homo sapiens], and cytoglobin isoform X2 [Homo sapiens].

**Q4.** Now, we'd like to search for more distant homology, using another iteration of PSI-BLAST (click the "Run" button). Were you able to find any other proteins? If so, what were they and what function do they perform?

**Q5.** Perform a third iteration. Did the algorithm find any other proteins? Did we find myoglobin and neuroglobin?

### **Section 3: Examining conservation patterns and evolutionary relationships**

It can be difficult to visually identify conserved regions in the regular online NCBI BLAST alignment display. Selecting alternative display formats can be helpful. Toward the top of your results page under "**Other reports**" click the "**Multiple alignment**" option (see image below).

This will submit your identified (or selected subset) of sequences for multiple alignment. On the resulting page scroll down past the “*Graphical Overview*” and “*Descriptions*” to the “*Alignments*” section and note the coloring by conservation. Change this to **Conservation Setting: Identity**.

**Q6.** Are there any invariant amino acid positions across all the globins that you have identified? If so how many positions, and what amino acids are these in relation to beta globin? **Hint:** A common way to write these results in terms of the one-letter amino acid code and position number in the sequence you care most about e.g. H64 for Histidine in position 64.

**Q7.** What do you think these invariant amino acid residues might do in all these globins?

At the very top of the page you can find a **Phylogenetic Tree** and **Download** link for your results. A common format to download is “Fasta plus gaps”. You can then open this downloaded file in a program such as Seaview (that we used in lab 1) or input to **R** as we will use next day.

Feel free to examine the “**Phylogenetic Tree**” link and discuss with your neighbors, IAs and Barry whether this makes sense based on what we now know about relationships between these globins.

#### **Section 4: Using HMMER** (OPTIONAL: Note server can be very slow - If so skip to section 5)

HMMER is an alternative sequence search and alignment method that employs probabilistic models called profile hidden Markov models (HMMs). HMMER aims to be significantly more accurate and more able to detect remote homologs than BLAST because of the strength of its underlying mathematical models. In the past, this strength came at significant computational expense, but in the new HMMER3 project, HMMER is now essentially as fast as BLAST.

Lets use the new HMMER3 online @ <http://www.ebi.ac.uk/Tools/hmmer/search/phmmer> to examine how results compare to those obtained from BLAST and PSI-BLAST in the last section.

**Q8.** Performing a HMMER (phmmer) search with our HBB sequence above against the **SwissProt** database and setting the “**Restrict by Taxonomy**” to **9606**, how do your results compare to those from regular BLAST and PSI-BLAST?

Results from a HMMER Search have much lower e-values than the regular BLAST and even PSI-BLAST searches, which is more promising of true positive homologs. Also, PSI-BLAST searches have “predicted” results when more iterations are ran. These results are probable, and therefore unreliable. However, HMMER doesn't have these, but yields approximately same # of results.

**Q9.** Did you find myoglobin and neuroglobin? Are there any neuroglobin PDB structures available? If so take a record of their PDB codes for later.

**Q10.** How long did your search take? **Was the web server accessible and responsive?**

HMMER is at the forefront of sequence-only based methods for detecting distant relatives. This tool is used to construct the **PFAM** (protein families) database. Find the link to the PFAM entry for the **Globin** family from your HMMER search results. Click on the HMM Logo link and determine the most conserved residues in this family.

**Q11.** Inspect the **HMM Logo** link for the PFAM Globin family and determine the most conserved residues in this family. Again the key question is what role might these residues play in these proteins?

In the molecular figure of beta globin above I have colored each residue position by the level of conservation in the alignment obtained from HMMER (blue - least conserved, red - most conserved). This information should help you answer Q11.

**Note:** If the HMMER web server was unresponsive you can search PFAM directly @ <https://pfam.xfam.org> to help answer Q11.

### Section 5: Divergence of protein sequence and protein structure during evolution

In this case, as in many other examples in the twilight zone, protein structure can yield important insights. This is primarily because protein structure similarities remain robust as sequence similarities fade during the course of evolution. If protein structures are available for your tentative homologues it is advisable to examine their structural similarity and the overlap of conserved sequence regions at potentially functional sites. We will cover this important topic in more detail in a later class. For now we will use the FATCAT **pairwise structural alignment** server to examine the similarities of our beta globin and neuroglobin proteins.

Visit: [http://fatcat.godziklab.org/fatcat/fatcat\\_pair.html](http://fatcat.godziklab.org/fatcat/fatcat_pair.html) and enter the *PDB code 2HBS chain B* for the first structure. Then enter one PDB code for neuroglobin you found from answering **Q17** previously (see below for an example).

Click **SUBMIT** to run the calculation and view the resulting structure *superposition* (basically a fit of one structure onto the other) online in their "**Interactive viewer**" by clicking the green arrow (see below):

Note how similar in structure these two distant homologues are.

Explore the different display options on this page. For the image here I have selected *Render as:* **cartoon** and *Color by:* **chain**. This has the effect of having the first chain colored blue and (that is our beta globin) and the second (neuroglobin) dark yellow.

**Q12.** Can you find the most divergent in structure regions? Where are they located in the structure (interior/exterior in secondary structure elements or loops)?

**Take home:** Unfortunately, we won't always have a structure available for the system under investigation but when we do they can provide invaluable insight into evolutionary and functional mechanisms.

**Q13.** What one part of this lab or associated lecture material is still confusing?  
Please answer in the following anonymous form: <https://forms.gle/FEbKxnq4X7nUMhcn8>
